Nurhakim S. 2003. Analysis of demersal assemblages off the north coast of Central Java, Indonesia, p. 187 - 206. In G. Silvestre, L. Garces, I. Stobutzki, M. Ahmed, R.A. Valmonte-Santos, C. Luna, L. Lachica-Aliño, P. Munro, V. Christensen and D. Pauly (eds.) *Assessment, Management and Future Directions for Coastal Fisheries in Asian Countries*. WorldFish Center Conference Proceedings 67, 1 120 p.

Abstract

Trawl survey data collected by the RV Mutiara 4 in 1979 off the north coast of Central Java (Indonesia) were used to examine the composition and distribution of species assemblages in the area. Classification (TWINSPAN) and ordination (DCA) techniques commonly used in community structure analysis were utilized during the study. The results indicate the existence of "shallow" and "deep" assemblages with a boundary at around 20 - 30 m depth (varying with the monsoon season). There is some consistency in the assemblages between the seasons.

Introduction

The waters off the north coast of Central Java (Fig. 1) are exploited not only by traditional fishers but also by commercial shrimp trawlers. Trawling started to increase in 1970 when shrimp trawlers expanded their fishing grounds from the Malacca Straits and Southern Java. In 1980, a Presidential Decree banned the operation of trawlers. Most of the trawlers converted to purse seining which developed rapidly in the Java Sea. Traditional fishers, with operations limited to near the coast (< 80 km), continued to exploit the demersal and shrimp species using traditional fishing gear. The presence of a fishing port and other facilities along the north coast of central Java are conducive to the concentration of traditional fishers in this area.

Intensive trawl surveys were conducted from 1974 to 1979 by the Indonesian-German Demersal Fisheries Project. After the ban on trawl operations in 1980, irregular surveys were done by the Research Institute for Marine Fisheries. (Bianchi et al. 1996) examined the demersal fish assemblages of the Java Sea using the 1974 - 76 survey data. Their

results show that the Java Sea has at least three demersal assemblages: one assemblage in the central and one in the deep part of the basin (> 30 m), and the shallow coastal assemblage.

This paper analyzes data from trawl surveys conducted off the north coast of central Java Sea in 1979 using methods commonly used in community structure analysis. It aims to investigate the distribution of demersal assemblages and their species composition.

Materials and Methods

This study focused on waters off the north coast of central Java Sea (Fig. 1). Data were collected using the wooden stern trawler RV Mutiara 4 (24.52 m LOA, 100 GT, 286 HP). The trawl used was the "Thailand trawl" with headline and footrope length of 35 m and 42.2 m respectively. The cod-end mesh size was 40 mm with a 22 mm cod-end insert net. Average trawling speed was 5.4 km·hr⁻¹ and the vertical net opening was estimated at 2 m. Most

of the hauls lasted one hour and were made during daylight hours (from 0500 H to 1800 H).

A total of 144 hauls were made during the 6 cruises conducted in the area in 1979 (Table 1). Catches were sorted up to species level for “food” fish (economically important) species and to families for “trash” fish. Environmental data (i.e. sea temperature, turbidity, depth) were collected for each haul.

The data from the 144 stations were grouped into seasons based on current understanding of monsoon seasonality in the study area. This process resulted in 3 temporal station groupings, namely: (1) West Monsoon (18 stations sampled in January and February); (2) Intermonsoon I (71 stations in April and May); and (3) Intermonsoon II (55 stations in September and October). No data are available for the East Monsoon season given the absence of cruises during June to August 1979. Each monsoon season is characterized by different environmental conditions, thus analysis was done separately by season.

The station-species/group matrices for each of the

three temporal groups were analyzed using Two-Way Indicators Species Analysis, or TWINSpan (Hill 1979), and Detrended Correspondence Analysis (DCA) using the CANOCO software (Ter Braak 1988). There was no data transformation done prior to analysis using TWINSpan and CANOCO.

Table 1. RV Mutiara 4 cruises in waters off the north coast of Central Java in 1979.

Cruise No.	Date	No. of Stations
01/79	12 - 13 January	7
03/79	19 - 20 February	11
04/79	26 - 30 April	27
05/79	10 - 24 May	44
09/79	9 - 10 September	11
11/79	12 - 18 October	44
TOTAL	12 Jan - 18 Oct	144

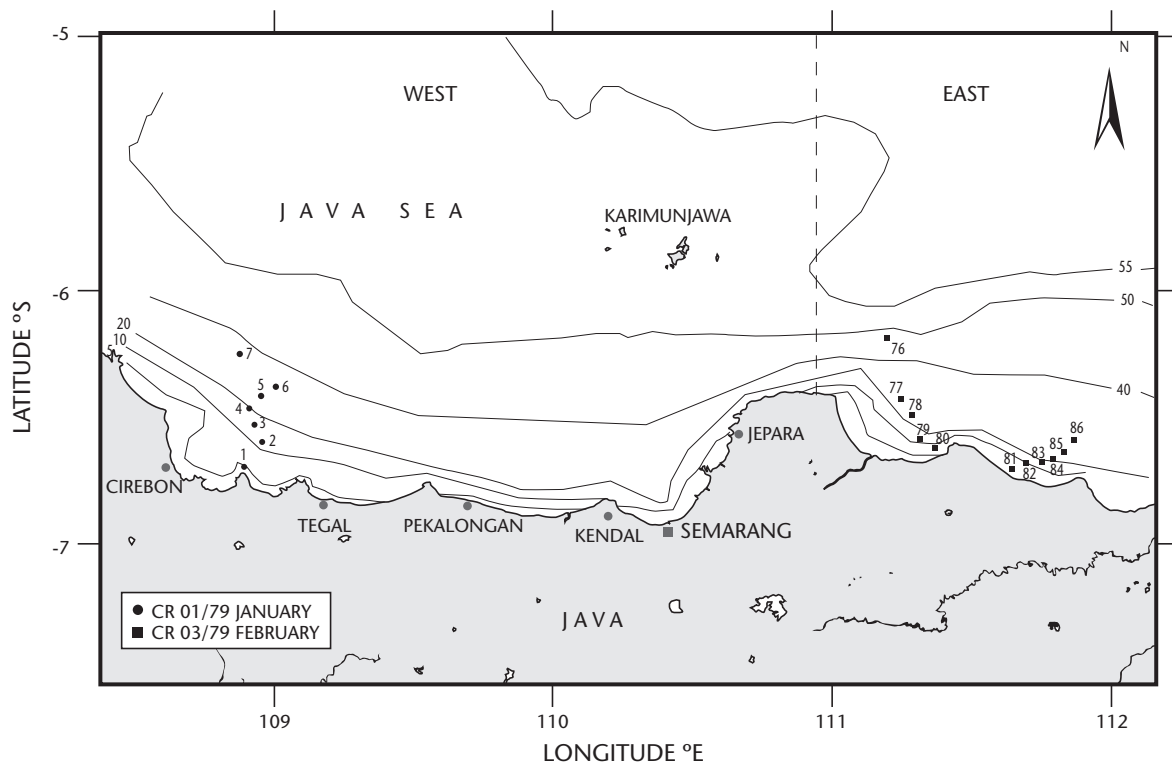

Fig. 1. Map of waters off the north coast of Central Java.

Results and Discussion

The two-way table generated from TWINSpan and the ordination plot from DCA for the January and February (west monsoon period) trawl stations is given in Table 2 and Fig. 2 respectively. Two groups of stations were evident, each with a characteristic species composition. The first group (Table 2, Group A) consists of eleven stations, characterized by areas with depths of more than 20 m while the second group (Table 2, Group B) consists of seven stations associated with the shallow/coastal waters (< 20 m) (Fig. 3).

There are notable differences in species composition between the shallow and deep-water stations (Table 2). The taxa in species cluster 1a include, among others, of *Lutjanus sanguineus*, *Pomadasys argyreus*, *Pomadasys hasta*, *Scolopsis* spp. and *Abalistes stellaris*. These were observed to be absent in shallow water stations. Taxa in species cluster 2d consisting of Sciaenidae, Muraenidae and *Anodontostoma* spp. which were absent in deep water stations. Some taxa (e.g. species cluster 1d) species cluster such as *Priacanthus* spp., *Pentaprion longimanus*, Sphyraenidae, *Arius thalassinus* and *Nemipterus japonicus* were relatively more abundant in deep compared to shallow water stations.

Fig. 3. Trawl stations off the north coast of Central Java in January and February 1979 showing station clusters derived using TWINSpan and DCA.

In contrast, taxa belonging to species cluster 2c were more abundant in the shallower stations than the deeper ones. It appears that taxa in species cluster 1c, 1d, 2a and 2b have almost the same abundance in both shallow and deep water stations. However, abundance of taxa in species cluster 2 preferred the deep stations (Table 3). Lactaridae, *Scomberomorus* spp., *Rastrelliger* spp., squid and *Leiognathus splendens* which belong to species cluster 1d were abundant both in shallow and deep stations; they are ubiquitous species/groups.

During the intermonsoon I period (April and May 1979), 65 stations were included in the analysis. Two main station clusters were formed. The first cluster included stations with depth of less than 25 m, and the second cluster included stations in depths of 25 to 45 m (see Table 3, Figs. 4 and 5).

The species/groups in species cluster 1a, 1b and 1c preferred shallow waters below 25 m. Species/groups in species cluster 1a were abundant at depths < 20 m, but rare at stations with depths greater than 20 m. Species/groups in species cluster 2 preferred the deep stations (Table 3). Lactaridae, *Scomberomorus* spp., *Rastrelliger* spp., squid and *Leiognathus splendens* which belong to species cluster 1d were abundant both in shallow and deep stations; they are ubiquitous species/groups.

In species cluster 2, *Upeneus sulphureus*, *Stolephorus* spp. and *Pentaprion longimanus* were more abundant at 35 to 45 m deep stations. Serranidae, *Charcharinus sealea*, Pentapodidae, *Abalistes stelar* and *Nemipterus margiatus* were observed to be absent at shallow water stations (< 25 m depth).

A total of 49 stations were finally included in the analysis for the intermonsoon II period (September and October 1979). Two major groups of stations were observed (Table 4, Figs. 6 and 7). One group was associated with shallow water stations (0 - 30 m) and the other group was associated with stations of more than 30 m depth. Some species in species cluster 1a, such as *Gazza minuta*, *Arius maculatus*, *Leiognathus equulus*, *Ilisha* spp., *Arius caelatus*, *Pomadasyd hasta*, Drepanidae, and Polynemidae were abundant in shallow stations. Some species in species cluster 2d such as *Abalistes stelaris*, *Atule* spp. *Lutjanus sanguineus*, *Scolopsis* spp. and *Nemipterus nemurus* were found mainly in deep stations.

Taxa which belong to species cluster 1d, 2a and 2b were found to have the same abundance in shallow and deep water stations (e.g., *Leiognathus splendens*, *Priacanthus* spp., *Sphyræna* spp.). These ubiquitous species/groups dominate catches in the study area. Species/groups that were abundant in shallow water stations (and rare in deep waters) include Dasyatidae, *Alectis indicus*, Sciaenidae, *Sardinella* spp., *Anadontostoma* spp. *Stolephorus* spp. Lactaridae, Stromatidae, *Thryssa* spp. and *Leiogna-*

thus brevirostris (species cluster 1b). Species/groups which belong to species cluster 2c, such as *Priacanthus tayenus*, *Nemipterus mesoprion*, *Atropus atropus*, *Upeneus sulphureus*, *Pentaprion longimanus*, *Selaroides leptolepis*, *Selar* spp. and *Leiognathus bindus* were more abundant in deep than in shallow stations. A summary of the most important species/groups comprising the shallow and deep assemblages during the three time periods considered here is given in Table 5 and 6. The species clusters were observed to be similar across seasons (i.e. there is consistency in taxa associated with the shallow versus deep stations).

The scope of the present study was limited by data constraints. These include the design of the trawl survey in 1979, the sorting and identification of catches, and availability of relevant environmental data. Best use of the data was attempted despite these constraints and has produced some insight into the species assemblages in the region. The results indicate the existence of shallow and deep and shallow assemblages with a boundary at around 20 - 30 m depth. This is consistent with the findings of (Bianchi et al. 1996).

Table 6. Catch rate and relative abundance of the 30 most important species/groups comprising the shallow and deep assemblages during the intermonsoon II period.

Deep			Shallow		
Species/Group	kg·h ⁻¹	%	Species/Group	kg·h ⁻¹	%
<i>Leiognathus splendens</i>	12.88	10.53	<i>Leiognathus splendens</i>	55.84	30.98
<i>Priacanthus</i> spp.	11.47	9.38	Dasyatidae	9.67	5.36
<i>Priacanthus macracanthus</i>	8.45	6.91	<i>Alepes</i> spp.	9.36	5.19
<i>Upeneus sulphureus</i>	8.26	6.75	<i>Arius caelatus</i>	8.30	4.60
<i>Pentrapion longimanus</i>	7.11	5.81	Other Food Fish	8.07	4.48
Trash Fish	6.52	5.33	Trash Fish	7.86	4.36
<i>Rastrelliger</i> spp.	4.30	3.51	Sciaenidae	7.39	4.10
<i>Lutjanus sanguineus</i>	4.23	3.46	Other Leiognathidae	6.04	3.35
Dasyatidae	3.91	3.19	<i>Pomadasys hasta</i>	4.91	2.72
Other Leiognathidae	3.42	2.80	<i>Rastrelliger</i> spp.	4.82	2.68
<i>Arius thalassinus</i>	3.38	2.76	Stromateidae	3.94	2.19
<i>Dussumieria acuta</i>	3.30	2.69	<i>Dussumieria acuta</i>	3.61	2.00
Other Carangidae	2.54	2.07	<i>Anadontostoma</i> spp.	3.14	1.74
<i>Selaroides leptolepis</i>	2.32	1.90	<i>Sardinella</i> spp.	2.58	1.43
<i>Nemipterus japonicus</i>	2.32	1.90	Sphyraenidae	2.19	1.22
<i>Megalaspis cordyla</i>	1.95	1.59	<i>Scomberomorus</i> spp.	1.96	1.09
<i>Selar</i> spp.	1.94	1.58	<i>Megalaspis cordyla</i>	1.94	1.08
Other Food Fish	1.84	1.50	<i>Stolephorus</i> spp.	1.89	1.05
Sphyraenidae	1.79	1.46	<i>Leiognathus equulus</i>	1.80	1.00
<i>Priacanthus tayenus</i>	1.41	1.15	<i>Alectis indicus</i>	1.75	0.97
Squids	1.39	1.13	<i>Leiognathus brevirostris</i>	1.72	0.95
Other Nemipteridae	1.36	1.11	<i>Thryssa</i> spp.	1.66	0.92
<i>Leiognathus bindus</i>	1.27	1.04	Theraponidae	1.61	0.89
<i>Scomberomorus</i> spp.	1.27	1.04	<i>Upeneus sulphureus</i>	1.58	0.87
<i>Alepes</i> spp.	1.26	1.03	Drepanidae	1.46	0.81
Synodontidae	1.19	0.97	<i>Arius thalassinus</i>	1.45	0.80
Scianidae	1.17	0.96	<i>Osteogeneosis milit</i>	1.42	0.79
Other Rays	1.10	0.90	Squids	1.42	0.79
<i>Arius venosus</i>	1.06	0.87	Other Carangidae	1.27	0.70
Snakes	0.90	0.74	<i>Priacanthus</i> spp.	1.19	0.66
Others	16.72	13.60	Others	18.07	10.03
