### Abstract

Catch, fishing effort, catch composition and species composition of small pelagic landings were monitored at six sites in the Philippines between 1987 to 1988. This data volume presents total monthly catch and fishing effort plus catch composition for all gears monitored over this period. Since commercial fishing vessels of a single type may vary greatly in gross tonnage, percentage contribution to the catches by different tonnage classes are given separately.

OCT 27 '88

## Introduction

This data volume summarizes information on catch and fishing effort for Philippine small pelagic fisheries between February 1987 to March 1988. The data were collected during the sampling period of the Small Pelagics Management project. This project was established by the Department of Agriculture and the Bureau of Fisheries and Aquatic Resources with the International Center for Living Aquatic Resources Management as the executing agency. Small pelagic fishes comprise about 25% of the total fish landings in the Philippines and are a cheap plentiful source of protein to poor 70% majority of the population. Despite the social and economic importance of these fishes, little contemporary data has been gathered on catch rates and catch composition. These data are important to determine stock assessment parameters for exploited fish populations and to cost and earnings of different vessel/gear type combinations.

Sampling of small pelagic landings was done at six fish landing sites in the Philippines. The locations of the six sites are shown in Fig. 1, along with the associated fishing grounds. The figures in parenthesis in Fig. 1 refer to the number of gears for which data were collected. In all, records of the landings of small pelagics caught by 22 different gear types were recorded. The records for the different data sets vary in quality considerably, particularly where sampling teams were faced with a large variety of gears. Effort is generally

recorded in hauls, except for six municipal gears where hours or days spent fishing were reported instead. These data sets are in any case marginal and of little use.

The total recorded catch and fishing effort for commercial and municipal gears are summarized on a monthly basis and presented as sets of tables following this short text. No effort data was recorded for vessels landing fish at the Navotas Fish Port Complex near Manila. All landings came from carrier vessels which service the various fishing boats. The catch is broken down into familial or generic groupings using the common English names. Since these are abbreviated, a key to the common and scientific names is given in Table 1. Where no catch composition data were available, then these catches are recorded separately. This was a particular problem with the data on trawl and purse seine landings in Bacolod. A companion to this data volume will be produced later which details species composition by gear month and location based on the sample data.

It is important to understand that in the following summaries, catch and effort data are not broken down into vessel size classes other than the conventional separation into commercial and municipal vessel/gears. 'Commercial' vessels are those of  $\geq 3$  G.T. whilst 'municipal' refers to vessels of  $< 3$  G.T. The 3 G.T. demarcation is a purely arbitrary classification that was originally used to define commercial fishing for

taxation and licensing purposes. A more detailed breakdown of catch and fishing effort by vessel gross tonnage class will be made later. Data are presented here, however, on the relative catch contribution by the different gears tonnage classes of commercial fishing vessels following the catch and effort summaries.

Details of the species composition of the catch are given in a series of tables following the catch and effort data for different vessel gross tonnages. The species composition data in this instance is simply the weight in grams each month of the different species sampled. This can be transformed to give the percent changes of species composition in the samples each month. However, this does not represent the species composition in the catch. To obtain this, the sample weights must be raised to the catch, then totalled over the sampling period to determine the true species composition. Since this is primarily a data volume, the results of this procedure will be reported elsewhere.

Table 1 Key to the catch composition of Philippine small pelagic fisheries.
